Compare the performance of the baseline model (Task 1) vs the fine-tuned model (Task 3). Briefly explain:

- Both the baseline and fine-tuned models correctly identified 9/10 digits, with digit 4 failing in both cases. However, there were notable differences in confidence scores. The baseline model showed high confidence (127) for most digits but struggled with digit 5 (score: 67). After fine-tuning, digit 5 improved significantly (score: 104), but some previously high-confidence digits like 6 (from 127 to 103) and 7 (from 127 to 111) saw slight confidence drops.

Overall, neither model was strictly better across all digits. The baseline performed with higher peak confidence on several digits, while the fine-tuned model was more consistent and balanced across all gestures. Fine-tuning did help for digit 5 specifically, which aligns with my gesture style, suggesting that the baseline model's training data may not fully capture my way of drawing 5. The persistent failure on digit 4 in both models indicates that my gesture style for 4 is consistently different from what either model learned, maybe because of how I start or end the stroke.
